

# **CSC 405**

# **Introduction to Computer Security**

## **Web Security**

Alexandros Kapravelos  
akaprav@ncsu.edu

(Derived from slides by Giovanni Vigna)

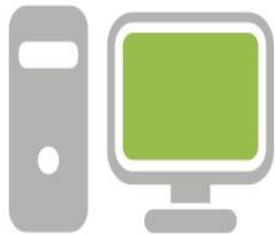

# Logic Flaws

- Logic flaws come in many forms and are specific to the intended functionality and security policy of an application
- Received little attention
  - Are known to be hard to identify in automated analysis
  - Not much public information
- Are on the rise: “...as the number of common vulnerabilities such as SQL injection and cross-site scripting are reduced, the bad guys are increasing their attacks on business logic flaws” [J. Grossman, WhiteHat Security]

# Fear the EAR

- Execution-After-Redirect vulnerabilities are introduced when code is executed after producing a redirect header
- The developer assumes that since a redirection occurred, code execution stopped
  - Redirect used as a goto
- Normally the behavior is invisible to the user, because the browser automatically load the page referenced by the redirection

# HTTP Redirects

GET /user/info HTTP/1.1  
Host: example.com

HTTP/1.1 302 Moved  
Location: <http://example.com/login>

GET /login HTTP/1.1  
Host: example.com

# Execution After Redirect: Example

```
class TopicsController < ApplicationController
  def update
    @topic = Topic.find(params[:id])
    if not current_user.is_admin?
      redirect_to("/")
    end
    @topic.update_attributes(params[:topic])
    flash[:notice] = "Topic updated!"
  end
end
```

# EAR History

- 17 Common Vulnerabilities and Exposures (CVE)
  - Starting in 2007
  - Difficult to find – no consistent category
- Blog post about Cake PHP 2006
  - Resulted in a bug filed and documentation changed
- Prior work on logic flaws
  - Found EAR in J2EE web application
- No one recognized it as a systemic logic flaw amongst web applications

# Types of EARs

- Benign
  - The state of the web application does not change
  - No leak of sensitive information
- Vulnerable
  - Allows for the unauthorized modification of the application state or discloses unauthorized data

# EAR: Information Leakage

```
<?php
$current_user = get_current_user();
if (!$current_user->is_admin())
{
    header("Location: /");
}
echo "457-55-5462";
?>
```

# Prevention

- Secure design
  - Django, ASP.NET MVC
- Terminate process or thread
  - ASP.NET, CakePHP, Zend, CodeIgniter
- Patched Ruby on Rails
  - Exception handling

# Attacking HTTP Protocol Implementations

- HTTP protocol heavily scrutinized
- HTTP protocol implementations might be erroneous
- Examples:
  - HTTP response splitting
  - HTTP request smuggling

# HTTP Response Splitting

- HTTP response splitting exploits the fact that user provided data is included in the header of a reply
- See: “HTTP Response Splitting, Web Cache Poisoning Attacks, and Related Topics” by A. Klein

# Redirection Example

- /redir\_lang.jsp

```
<%  
response.sendRedirect("/by_lang.jsp?lang="+  
    request.getParameter("lang"));  
%>
```

- For example calling with “lang” set to “English” will create the following redirect

```
HTTP/1.1 302 Moved Temporarily  
Date: Tue, 17 Nov 2015 12:53:28 GMT  
Location: http://10.1.1.1/by_lang.jsp?lang=English  
...
```

```
<html>Error...</html>
```

# Response Splitting

- What if we call:  
`/redir_lang.jsp?lang=foobar%0d%0aContent-  
Length:%200%0d%0a%0d%0aHTTP/1.1%20200%200K%0d%0aContent-  
Type:%20text/html%0d%0aContent-  
Length:%2019%0d%0a%0d%0a<html>Shazam</html>`
- If the server includes the value of the “lang” variable verbatim, the resulting answer may appear as two different replies
- If the attacker includes a request for /index.html, the second (fake) reply will be associated with it, possibly poisoning an intermediate cache

# The Response Output

```
HTTP/1.1 302 Moved Temporarily
```

```
Date: Tue, 17 Nov 2015 15:26:41 GMT
```

```
Location: http://10.1.1.1/by_lang.jsp?lang=foobar
```

```
Content-Length: 0
```

```
HTTP/1.1 200 OK
```

```
Content-Type: text/html
```

```
Content-Length: 19
```

```
<html>Shazam</html>
```

```
...(ignored stuff here)
```

- From now on an intermediate proxy will associate the second reply with /index.html

# HTTP Request Smuggling

- This attack exploits the difference in the parsing procedures performed by different components in the request delivery process
- For example, request is forged to confuse proxy and desynchronize its view from the view of the server
- See “HTTP Request Smuggling” by C. Linhart et al.

# HTTP Request Smuggling

```
1  POST http://SITE/foobar.html HTTP/1.1
2  Host: SITE
3  Connection: Keep-Alive
4  Content-Type: application/x-www-form-urlencoded
5  Content-Length: 0
6  Content-Length: 44
7  [CRLF]
8  GET /poison.html HTTP/1.1
9  Host: SITE
10 Bla: [space after the "Bla:", but no CRLF]
11 GET http://SITE/page_to_poison.html HTTP/1.1
12 Host: SITE
13 Connection: Keep-Alive
14 [CRLF]
```

# HTTP Request Smuggling

- Proxy
  - The proxy parses the POST request in lines 1-7, and encounters the two "Content-Length" headers
  - It decides to ignore the first header, so it assumes the request has a body of length 44 bytes
  - It treats the data in lines 8-10 as the first request's body. Then it parses lines 11-14, which it treats as the client's second request
- The server
  - Uses the first "Content-Length" header and believes that the first POST request has no body
  - The second request is the GET in line 8 (notice that the GET in line 11 is parsed by the server as the value of the "Bla" header in line 10)

# HTTP Request Smuggling

- The server sends back the content of
  - foobar.html
  - poison.html
- The proxy associates these requests to
  - POST /foobar.html
  - GET /page\_to\_poison.html
- From now on, every client asking for page\_to\_poison.html will receive poison.html, instead

# OWASP Top Ten Web Vulnerabilities

- **A1: Injection**
  - Injection flaws, such as SQL, OS, and LDAP injection, occur when untrusted data is sent to an interpreter as part of a command or query. The attacker's hostile data can trick the interpreter into executing unintended commands or accessing unauthorized data
- **A2: Broken Authentication and Session Management**
  - Application functions related to authentication and session management are often not implemented correctly, allowing attackers to compromise passwords, keys, session tokens, or exploit implementation flaws to assume other users' identities

# OWASP Top Ten Web Vulnerabilities

- **A3: Cross-Site Scripting (XSS)**
  - XSS flaws occur whenever an application takes untrusted data and sends it to a web browser without proper validation and escaping. XSS allows attackers to execute script in the victim's browser which can hijack user sessions, deface web sites, or redirect the user to malicious sites
- **A4: Insecure Direct Object References**
  - A direct object reference occurs when a developer exposes a reference to an internal implementation object, such as a file, directory, or database key. Without an access control check or other protection, attackers can manipulate these references to access unauthorized data

# OWASP Top Ten Web Vulnerabilities

- **A5: Security Misconfiguration**
  - Security depends on having a secure configuration defined for the application, framework, web server, application server, and platform. All these settings should be defined, implemented, and maintained as many are not shipped with secure defaults
- **A6: Sensitive Data Exposure**
  - Many web applications do not properly protect sensitive data, such as credit cards, tax IDs, and authentication credentials. Attackers may steal or modify such weakly protected data to conduct credit card fraud, identity theft, or other crimes. Sensitive data deserves extra protection such as encryption at rest or in transit, as well as special precautions when exchanged with the browser.

# OWASP Top Ten Web Vulnerabilities

- **A7: Missing Function Level Access Control**
  - Most web applications verify function level access rights before making that functionality visible in the UI. However, applications need to perform the same access control checks on the server when each function is accessed. If requests are not verified, attackers will be able to forge requests in order to access functionality without proper authorization
- **A8: Cross-Site Request Forgery**
  - A CSRF attack forces a logged-on victim's browser to send a forged HTTP request, including the victim's session cookie and any other authentication information, to a vulnerable web application. This allows the attacker to force the victim's browser to generate requests the vulnerable application thinks are legitimate requests from the victim

# OWASP Top Ten Web Vulnerabilities

- **A9: Using Known Vulnerable Components**
  - Components, such as libraries, frameworks, and other software modules, almost always run with full privileges. If a vulnerable component is exploited, such an attack can facilitate serious data loss or server takeover. Applications using components with known vulnerabilities may undermine application defenses and enable a range of possible attacks and impacts
- **A10: Unvalidated Redirects and Forwards**
  - Web applications frequently redirect and forward users to other pages and websites, and use untrusted data to determine the destination pages. Without proper validation, attackers can redirect victims to phishing or malware sites, or use forwards to access unauthorized pages

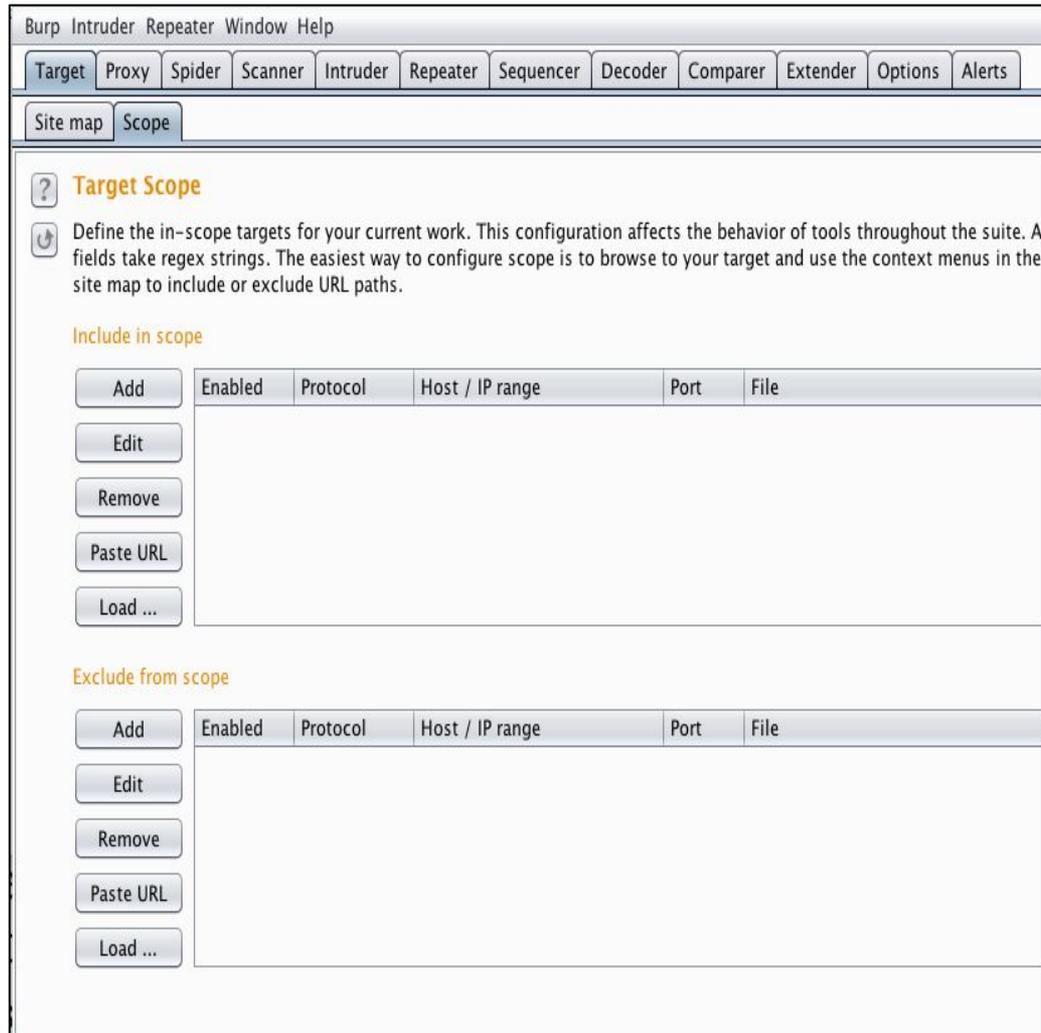

# Burp

- Security tool for the interception, analysis, and modification of web requests
  - Free version: No save and restore capability
  - Commercial version (\$299/year): adds vulnerability scanner
- Implemented in Java, runs on any platform
- The tool can be extended with custom modules

# Target Specification

- Supports the description of the allowed hosts/URLs
- Important to avoid inadvertent attacks to hosts reached through links

# Target Specification

The screenshot shows the 'Target Scope' configuration window in Burp Suite. The window title is 'Burp Intruder Repeater Window Help'. The menu bar includes 'Target', 'Proxy', 'Spider', 'Scanner', 'Intruder', 'Repeater', 'Sequencer', 'Decoder', 'Comparer', 'Extender', 'Options', and 'Alerts'. Below the menu bar, there are tabs for 'Site map' and 'Scope', with 'Scope' currently selected.

**Target Scope**

Define the in-scope targets for your current work. This configuration affects the behavior of tools throughout the suite. All fields take regex strings. The easiest way to configure scope is to browse to your target and use the context menus in the site map to include or exclude URL paths.

**Include in scope**

Enabled	Protocol	Host / IP range	Port	File
---------	----------	-----------------	------	------

Buttons: Add, Edit, Remove, Paste URL, Load ...

**Exclude from scope**

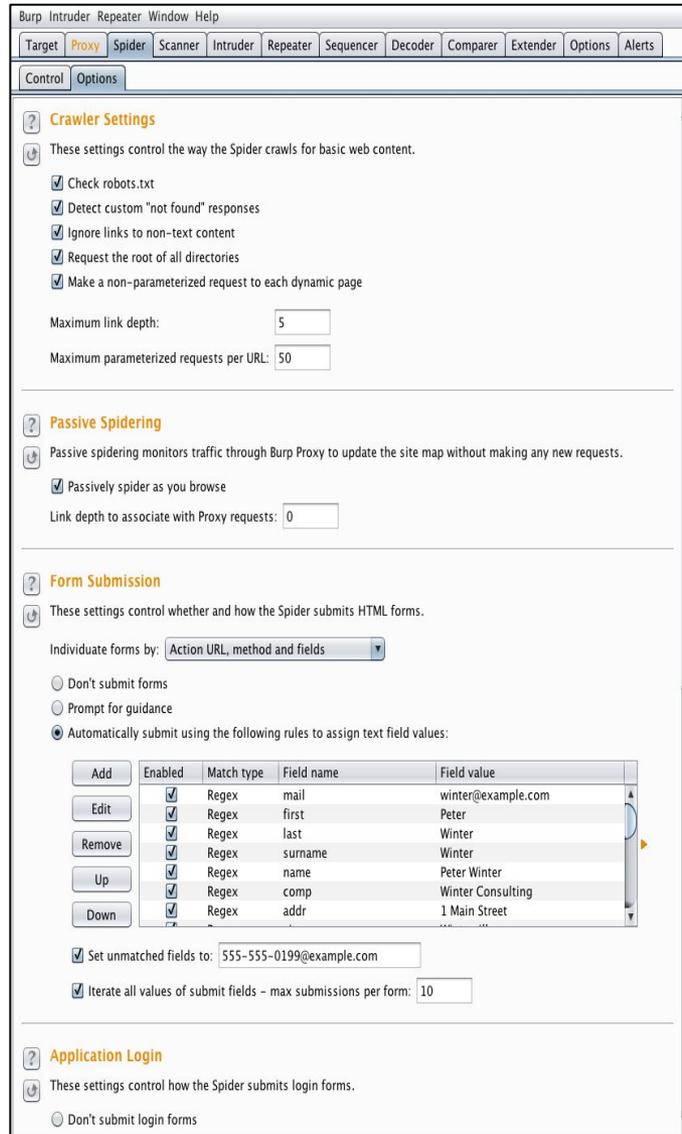

Enabled	Protocol	Host / IP range	Port	File
---------	----------	-----------------	------	------

Buttons: Add, Edit, Remove, Paste URL, Load ...

# Crawling

- Burp provides a crawling component (spider)
  - Can be active or passive
- Allows for the discovery of pages automatically
  - Supports the submission of forms
    - Not perfect, but great value for the price
    - See: “Why Johnny Can't Pentest: An Analysis of Black-box Web Vulnerability Scanners,” Adam Doupe, Marco Cova, Giovanni Vigna, in Proceedings of the Conference on Detection of Intrusions and Malware and Vulnerability Assessment (DIMVA), 2010

# Crawling

The screenshot shows the 'Spider' settings window in Burp Suite. The window has a menu bar with 'Burp', 'Intruder', 'Repeater', 'Window', and 'Help'. Below the menu bar is a tabbed interface with 'Target', 'Proxy', 'Spider', 'Scanner', 'Intruder', 'Repeater', 'Sequencer', 'Decoder', 'Comparer', 'Extender', 'Options', and 'Alerts'. The 'Spider' tab is active, and the 'Options' sub-tab is selected. The main content area is divided into three sections: 'Crawler Settings', 'Passive Spidering', and 'Form Submission'. Each section has a help icon, a title, and a description. The 'Crawler Settings' section includes checkboxes for 'Check robots.txt', 'Detect custom "not found" responses', 'Ignore links to non-text content', 'Request the root of all directories', and 'Make a non-parameterized request to each dynamic page'. It also has input fields for 'Maximum link depth' (5) and 'Maximum parameterized requests per URL' (50). The 'Passive Spidering' section has a checkbox for 'Passively spider as you browse' and an input field for 'Link depth to associate with Proxy requests' (0). The 'Form Submission' section has a dropdown for 'Individuate forms by' (Action URL, method and fields) and radio buttons for 'Don't submit forms', 'Prompt for guidance', and 'Automatically submit using the following rules to assign text field values:'. Below this is a table with columns 'Enabled', 'Match type', 'Field name', and 'Field value'. The table contains six rows of rules. At the bottom of the 'Form Submission' section, there are checkboxes for 'Set unmatched fields to:' (555-555-0199@example.com) and 'Iterate all values of submit fields - max submissions per form:' (10). The 'Application Login' section is partially visible at the bottom, with a radio button for 'Don't submit login forms'.

Spider Crawler Settings

These settings control the way the Spider crawls for basic web content.

- Check robots.txt
- Detect custom "not found" responses
- Ignore links to non-text content
- Request the root of all directories
- Make a non-parameterized request to each dynamic page

Maximum link depth:

Maximum parameterized requests per URL:

Passive Spidering

Passive spidering monitors traffic through Burp Proxy to update the site map without making any new requests.

- Passively spider as you browse

Link depth to associate with Proxy requests:

Form Submission

These settings control whether and how the Spider submits HTML forms.

Individuate forms by:

- Don't submit forms
- Prompt for guidance
- Automatically submit using the following rules to assign text field values:

Enabled	Match type	Field name	Field value
<input checked="" type="checkbox"/>	Regex	mail	winter@example.com
<input checked="" type="checkbox"/>	Regex	first	Peter
<input checked="" type="checkbox"/>	Regex	last	Winter
<input checked="" type="checkbox"/>	Regex	surname	Winter
<input checked="" type="checkbox"/>	Regex	name	Peter Winter
<input checked="" type="checkbox"/>	Regex	comp	Winter Consulting
<input checked="" type="checkbox"/>	Regex	addr	1 Main Street

Set unmatched fields to:

Iterate all values of submit fields - max submissions per form:

Application Login

These settings control how the Spider submits login forms.

- Don't submit login forms

# Proxy

- The proxy functionality allows for the interception and modification of requests

# Proxy

# Intruder

- Intruder allows one to perform simple fuzzing of a request
- Request is selected from history and forwarded to the module
- The parameters are substituted with placeholders
- The user specifies regular expression to be matched against the result of the request
- When activated the intruder perform a large number of requests, looking for possible error conditions

**?** **Grep - Match**

These settings can be used to flag result items containing specified expressions.

Flag result items with responses matching these expressions:

Paste error  
Load ... exception  
Remove illegal  
Clear invalid  
fail  
stack  
access  
directory

Add

Match type:  Simple string  Regex

Case sensitive match  
 Exclude HTTP headers

---

**?** **Grep - Extract**

These settings can be used to extract useful information from responses into the attack results table.

Extract the following items from responses:

Add   
Edit

# Repeater

- Allows for manual exploration of requests
- Request in history is sent to the module
- User can modify request and observe immediately the effect on the response

# Repeater

The screenshot displays the Burp Suite Repeater interface. At the top, the menu bar includes 'Burp', 'Intruder', 'Repeater', 'Window', and 'Help'. Below the menu is a toolbar with buttons for 'Target', 'Proxy', 'Spider', 'Scanner', 'Intruder', 'Repeater', 'Sequencer', 'Decoder', 'Comparer', 'Extender', 'Options', and 'Alerts'. The 'Repeater' button is highlighted. Below the toolbar, there is a tab labeled '1' and a 'Go' button. The target URL is 'http://www.cnn.com'. The interface is split into two main panes: 'Request' on the left and 'Response' on the right. The 'Request' pane has sub-tabs for 'Raw', 'Params', 'Headers', and 'Hex', with 'Raw' selected. The 'Response' pane has a 'Raw' tab. The 'Request' pane contains the following text:

```
GET / HTTP/1.1
Host: www.cnn.com
User-Agent: Mozilla/5.0 (Macintosh; Intel Mac
OS X 10.11; rv:41.0) Gecko/20100101
Firefox/41.0
Accept:
text/html,application/xhtml+xml,application/xml;
q=0.9,*/*;q=0.8
Accept-Language: en-US,en;q=0.5
Accept-Encoding: gzip, deflate

Connection: keep-alive
```

The 'Response' pane is currently empty. At the bottom of the interface, there are search bars for both the request and response, each showing '0 matches'.

# Sequencer

- Module that allows for the statistical analysis of tokens used in web applications
- Useful to determine the “randomness” of fields (esp. session IDs)

# Sequencer

The screenshot shows the Burp Suite Sequencer tool interface. The top menu bar includes 'Burp', 'Intruder', 'Repeater', 'Window', and 'Help'. Below the menu bar is a toolbar with buttons for 'Target', 'Proxy', 'Spider', 'Scanner', 'Intruder', 'Repeater', 'Sequencer', 'Decoder', 'Comparer', 'Extender', 'Options', and 'Alerts'. The 'Sequencer' button is highlighted. Below the toolbar is a sub-toolbar with buttons for 'Live capture', 'Manual load', and 'Analysis options'. The main content area is divided into two sections: 'Token Handling' and 'Token Analysis'. The 'Token Handling' section includes a help icon, a title, a description, and three settings: 'Pad short tokens at' (radio buttons for 'Start' and 'End'), 'Pad with (single character or 2-digit ASCII hex code):' (text input field with '0'), and 'Base64-decode before analyzing' (checkbox). The 'Token Analysis' section includes a help icon, a title, a description, and two groups of settings: 'Character level' (checkboxes for 'Count' and 'Transitions') and 'Bit level' (checkboxes for 'FIPS monobit', 'Spectral', 'FIPS poker', 'Correlation', 'FIPS runs', 'Compression', and 'FIPS long run').

Live capture Manual load Analysis options

? **Token Handling**

These settings control how tokens are handled during analysis.

Pad short tokens at:  Start  End

Pad with (single character or 2-digit ASCII hex code):

Base64-decode before analyzing

---

? **Token Analysis**

The options below control the types of analysis that is performed at the character level.

Count

Transitions

The options below control the types of analysis that is performed at the bit level.

FIPS monobit  Spectral

FIPS poker  Correlation

FIPS runs  Compression

FIPS long run

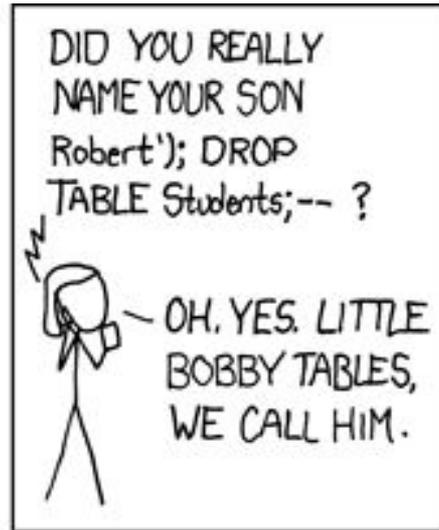

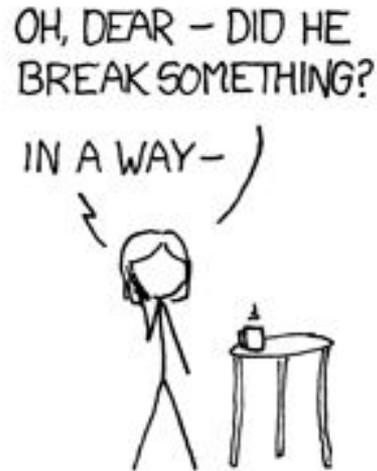

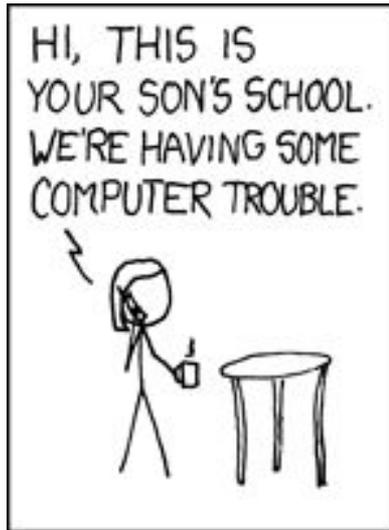

# Decoding and Comparing

- The Decoder module allows for the encoding and decoding of content
- The Comparer modules allows for the diffing of content

# Conclusions

- Web applications have become the way in which we store and manage sensitive information
- Web security is different from application security
  - Modules can be executed in any order
  - Modules can be invoked in parallel
- Often times the developers of traditional applications make erroneous assumptions when developing web applications

# Questions?

# Your Security Zen

Microsoft Office 0-day in the wild

All Office and Windows versions are vulnerable

Even Windows 10...

Patch is coming today

Reports say it was first seen in July!

You can block the attack by changing:

Software\Microsoft\Office\15.0\Word\Security\FileBlock\RtfFiles  
to 2 and OpenInProtectedView to 0
